

Part 1: Categories for the Description of Works of Art (CDWA)

Categories for the Description of Works of Art (CDWA)				
Development	Goals & Objectives	Principles	Domains	Architectural Layout
Developed in the 1990s by the Art Information Task Force (AITF) made up of art professionals across multiple art communities and funded by Getty Trust. Guidelines based on consensus within the user community to establish guidelines and best practices across art world.	Objectives: provide framework for the cataloguing and description of works of art, architecture and other cultural materials, collections of work and their related images that allows for easy identification, information retrieval, information migration, and interoperability	Principles: use of metadata standards crosswalk, data exchange across platforms, consistency through controlled vocabularies like Cultural Objects Name Authority (CONA)	Environmental domain: art and museum community Object class domain (genre): object/works, architecture and groups Formats: physical objects and their digital representations, digital objects, images, multimedia, text, audio, film, collections, buildings	Structural design: Relational data structure where works are linked in hierarchical relationships using authority files. Extent: 540 categories and subcategories with a small set of 31 core categories for the work itself, related text, creator identification, place, generic concept, and subject. Granularity: high granularity, intended for very specialized and in-depth catalog description

Part 2

I decided to use Metadata2go to extract metadata from a work file saved as a Word document and a downloaded jpg from a wallpaper website.

What it intends to accomplish: Metadata2go markets itself as a tool to extract hidden, embedded (EXIF) metadata from files.

Advantages/Disadvantages	How was metadata generated?	Recommendations for tool improvement
Advantages: speed and ease of extraction, consistency (same elements pulled for same file types), great at extracting administrative metadata. Can quickly pull title, file name, and creator from document properties. Ability to export the metadata to multiple file formats Disadvantages: lacking in descriptive metadata, no subject, keywords, or description extracted from within the text, creator has to meticulously and manually add this information to document properties beforehand for it to show up in metadata subject and keyword elements. Lack of organizational and relational context for how that file might exist in relation to other files and/or the repository it lives in.	Automatic extraction for both word document and jpg	- Ability to also extract subject metadata from format specified text like headings within document (I purposefully set text as heading 1 and heading 2 to see if the metadata extraction tool would pull from text). - The ability to crosswalk the provided fields to another (simple) metadata standard like Dublin Core and export it would be amazing!
